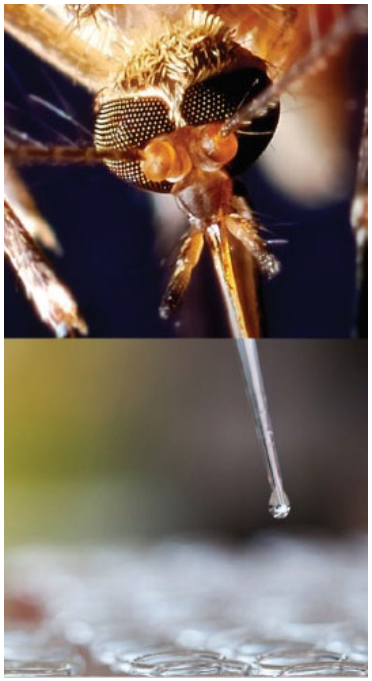
Professor, George Mason University

Credible Leads to Incredible™



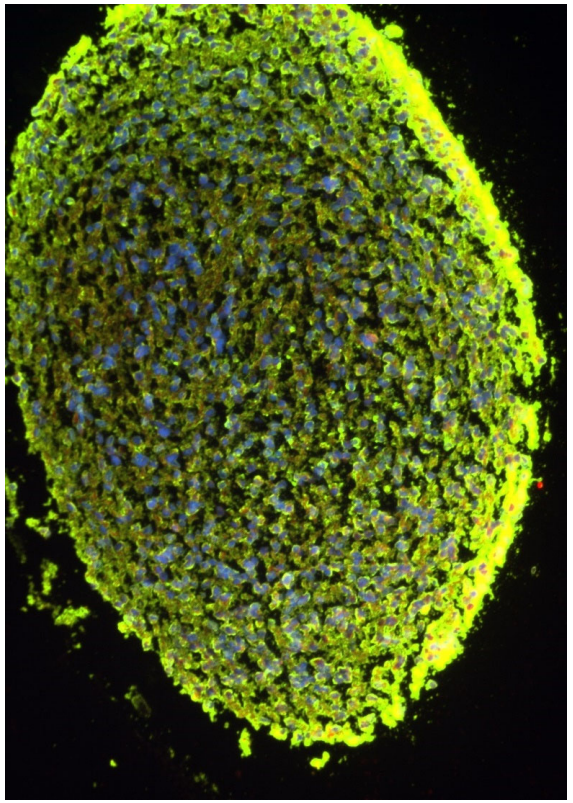
About ATCC

- Founded in 1925, ATCC is a non-profit organization with HQ in Manassas, VA, and an R&D and Services center in Gaithersburg, MD
- World's largest, most diverse biological materials and information resource for cell culture – the "*gold standard*"
- Innovative R&D company featuring gene editing, differentiated stem cells, advanced models
- cGMP biorepository
- Partner with government, industry, and academia
- Leading global supplier of authenticated cell lines, viral and microbial standards
- Sales and distribution in 150 countries, 19 international distributors
- Talented team of 450+ employees, over one-third with advanced degrees

ATCC®

Overview

- Update on the most recent literature surrounding EVs from virally infected cells (“Damaging EVs”)
- Generation and infection of iPSC-derived neurospheres
- Effect of stem cell EVs (“Reparative EVs”) on HIV-1 infected neurospheres
- Summary



Neural progenitor cell-derived neurosphere

Meeting of the American Society for Intercellular Communication

Mason Marketplace

It gives us great pleasure to annouce the 1st meeting of the **American Society for Intercellular Communication (ASIC)**

The meeting will be held on **October 21st – October 23rd 2021.**

The meeting is organized by a group of investigators seeking to create a platform for informal exchange of ideas on emerging questions and cutting-edge developments in the field of Extracellular Vesicles (EVs), Extracellular Particles (EPs), and particulate carriers of extracellular RNA (exRNA) as biological mediators, regulators and diagnostic analytes. Our program of relatively short talks (15 and 30 minutes) encourage discussions that can take place after each scientific talk, where the audience and attendees can debate the concepts presented to foster a dynamic scientific exchange.

We invite you to join us for a 3-day meeting (Thursday afternoon, all day Friday and Saturday until noon; October 21st – October 23rd) at the Bolger Center in Potomac, Maryland. The program will include the functions of EVs, EPs, exRNA in cancer, CNS diseases, infections (both bacterial and viral), the mechanistic basis for their biogenesis and activities, and technological and diagnostic advances in the field. *In the interest of everyone's health and safety, vaccines are required to attend this meeting in person. We will also be following CDC guidelines for this meeting.*

Late Breaking Abstracts are due by September 30, 2021

Late Breaking Registration: September 30, 2021

Maraviroc	1
Enfuvirtide	3

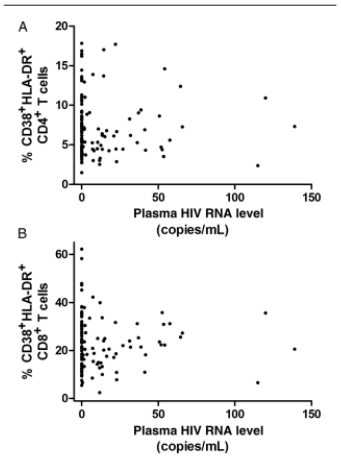

Figure 1. No associations between ultrasensitive plasma human immunodeficiency virus (HIV) RNA levels and T-cell activation. Ultrasensitive plasma HIV RNA levels were measured using the COBAS AmpliPrep/COBAS TaqMan HIV-1 test, version 2.0. All *P* values are >.40.

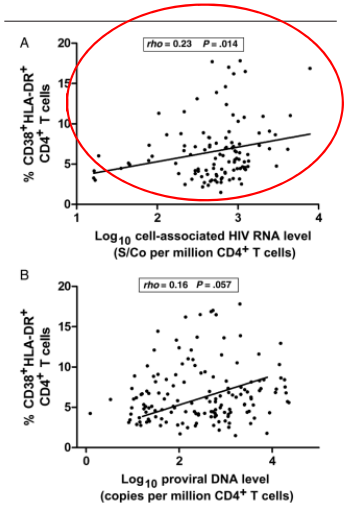

Figure 2. Cell-based measures of viral persistence are modestly associated with immune activation.

B)

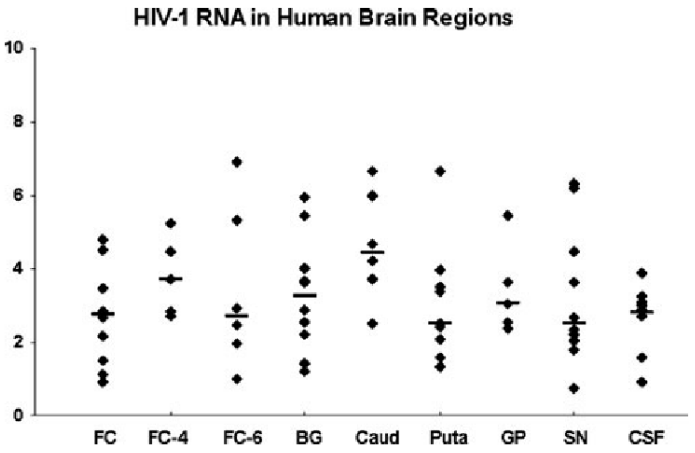

Figure 1 HIV-1 RNA load (log_{10} copies/g tissue) in each region of HIV-1+ individuals is presented in a scatter plot. The horizontal bars represent the median value in each region. Viral load values were higher in caudate nucleus compared to that in the other regions (FC-4, FC-6, BG, putamen, globus pallidus, SN), and the lowest values were found in FC and CSF.

HIV-1 and HAND

- HIV-associated neurocognitive disorders (HAND) are comprised of a range of neurological dysfunctions which are commonly associated with HIV-1 infection.
- Despite cART, HAND still persists in HIV-1 patients (>50%).
- Exosomes secreted from HIV-1 infected cells under cART can damage CNS cells (damaging exosomes).
  - Damaging exosomes contain viral non-coding RNA (TAR) and other viral proteins (Tat, Nef, Env) that cause neuroinflammation.
- Damaging exosomes have also been isolated from 6 other CNS tropic viral infections including HTLV-1, Zika, RVFV, Ebola, HSV-1, and HHV-6A.

Antiretroviral Drugs Alter the Content of Extracellular Vesicles from HIV-1-Infected Cells

Received: 3 January 2018
Accepted: 1 May 2018
Published online: 16 May 2018

Barclay[1], Yao Akpamagbo[1], James Erickson[1], Nicaise Ndembi[2], Manhattan Charurat[2], Jibreel Jumare[2], Sunday Bwala[3], Peter Alabi[4], Max Hogan[5], Archana Gupta[5], Nicole Noren Hooten[6], Michele K. Evans[6], Benjamin Lepene[7], Weidong Zhou[8], Massimo Caputi[9], Fabio Romerio[2], Walter Royal 3rd[10], Nazira El-Hage[11], Lance A. Liotta[8] & Fatah Kashanchi[1]

To date, the most effective treatment of HIV-1 is a combination antiretroviral therapy (cART), which reduces viral replication and reverses pathology. We investigated the effect of cART (RT and protease inhibitors) on the content of extracellular vesicles (EVs) released from HIV-1-infected cells. We have previously shown that EVs contain non-coding HIV-1 RNA, which can elicit responses in recipient cells. In this manuscript, we show that TAR RNA levels demonstrate little change with the addition of cART treatment in cell lines, primary macrophages, and patient biofluids. We determined possible mechanisms involved in the selective packaging of HIV-1 RNA into EVs, specifically an increase in EV-associated hnRNP A2/B1. More recent experiments have shown that several other FDA-approved drugs have the ability to alter the content of exosomes released from HIV-1-infected cells. These findings on cART-altered EV content can also be applied to general viral inhibitors (interferons) which are used to treat other chronic infections. Additionally, we describe unique mechanisms of ESCRT pathway manipulation by antivirals, specifically the targeting of VPS4. Collectively, these data imply that, despite antiretroviral therapy, EVs containing viral products are continually released and may cause neurocognitive and immunological dysfunction.

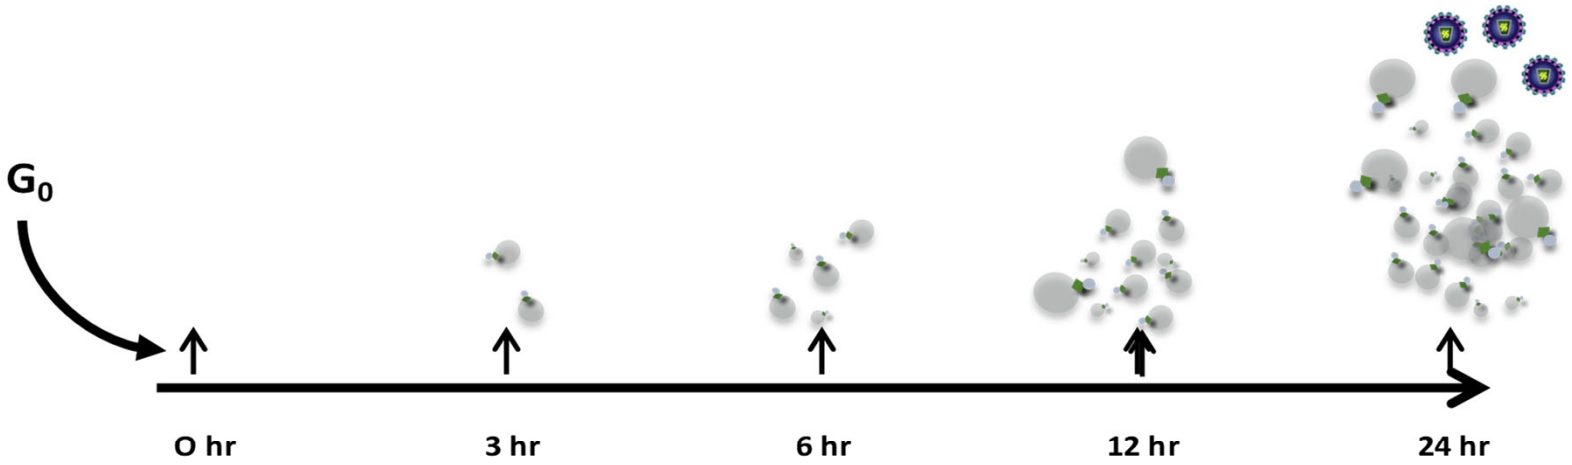
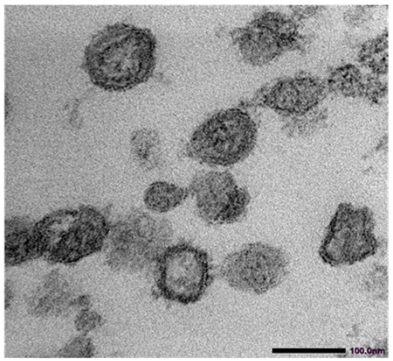
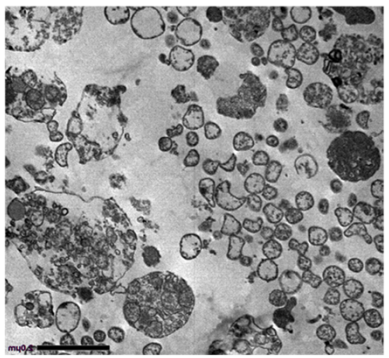
Answer: EVs come out of infected cells first and then a mixture of both EVs and viruses at a later time







Human T-lymphotropic virus type 1 (HTLV-1)

Epidemiology

- Approximately **5-10 million** patients worldwide infected with HTLV-1.
- The true figure is greater as many cases are unreported from highly populated regions, such as **China, India, Northwest Africa (i.e., the Arab Maghreb), and East Africa**.
- It is estimated that the actual global prevalence may be as **high** as **20 million** worldwide.

Stem cell EVs

- Contain various biological cargo (miRNAs, lncRNAs, proteins, cytokines) that can be transferred to recipient cells
- **Proposed to play a role in homeostasis through tissue repair, regeneration, and immunomodulation**
- Potential alternative to stem cell therapy due to higher potency, increased stability/shelf life, and lower immunogenicity
- Widely studied for reparative purposes (e.g., skin/wound healing, cardiac repair, **CNS-related pathologies**)

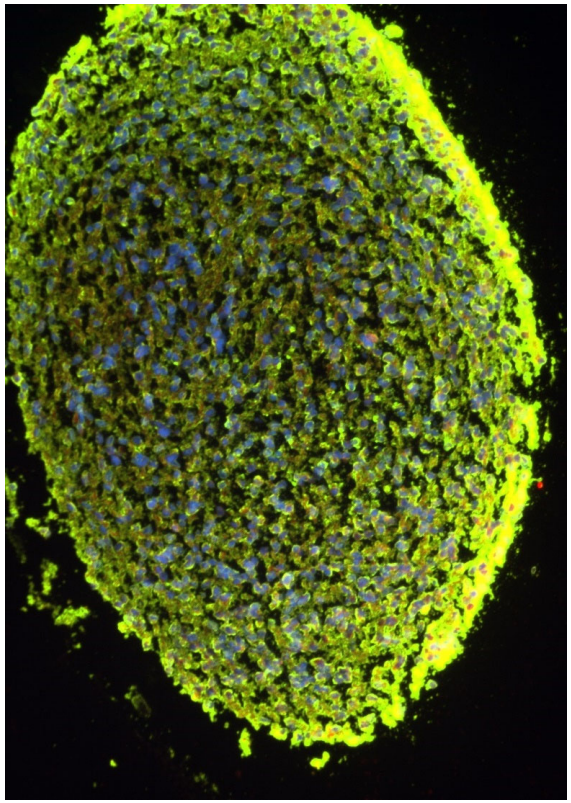
Overview

- Update on the most recent literature surrounding EVs from virally infected cells (“Damaging EVs”)
- Generation and infection of iPSC-derived neurospheres
- Effect of stem cell EVs (“Reparative EVs”) on HIV-1 infected neurospheres
- Summary



Summary

- HIV-1 TAR as non-coding RNA in EVs can be found in cell lines and patient samples.
- EVs are released first prior to viral release to potentially prime the neighboring uninfected cells.
- Early EV samples (i.e., 6 hours) contain p24, Nef, gp120 proteins, non-coding RNA, or coding RNAs; however, they are not infectious virions.
- The majority of the particles released (i.e., 24 hours) from infected activated cells are not infectious virions.
- NPC-derived 3-D neurospheres can be generated in a reproducible manner and can differentiate mature CNS cell types.
- 3-D neurospheres are permissive to retroviral infection.
- High yields of stem cell EVs can be recovered using advanced filtration methods.
- Stem cell EVs can exert functional effects in CNS-related cells in both 2-D and 3-D cultures.
